INTRODUCTION

- Colorectal cancer (CRC) is the second-leading cause of cancer-related death in the US, but is treatable when detected early¹
- Despite the proven benefits of CRC screening, recent statistics revealed over 40% of eligible adults at average risk for CRC in the US were not up to date with guideline recommended screening in 2021²⁻⁴
- Low screening uptake can partly be attributed to the inconveniences associated with existing screening methods and disparities in access to medical care among certain demographic groups^{2,5}
- Specific challenges of current screening modalities include bowel preparation and the invasiveness associated with colonoscopy (CS), and fecal aversion associated with stool-based tests⁶
- Ideally, comprehensive CRC screening should detect both small and large advanced colorectal neoplasia (ACN) and difficult-to-discern proximal lesions to increase the likelihood of achieving the best possible outcomes⁷
- Blood-based screening may offer a convenient alternative to traditional methods, and potentially increase screening uptake^{8,9}
- PREEMPT CRC (NCT04369053¹⁰), a prospective, multicenter, observational study, was conducted to validate an investigational CRC early detection blood test designed to detect molecular signals associated with ACN in an average-risk population

OBJECTIVE

- To analyze the performance of an investigational CRC early detection blood test by lesion location and size

METHODS

Study design

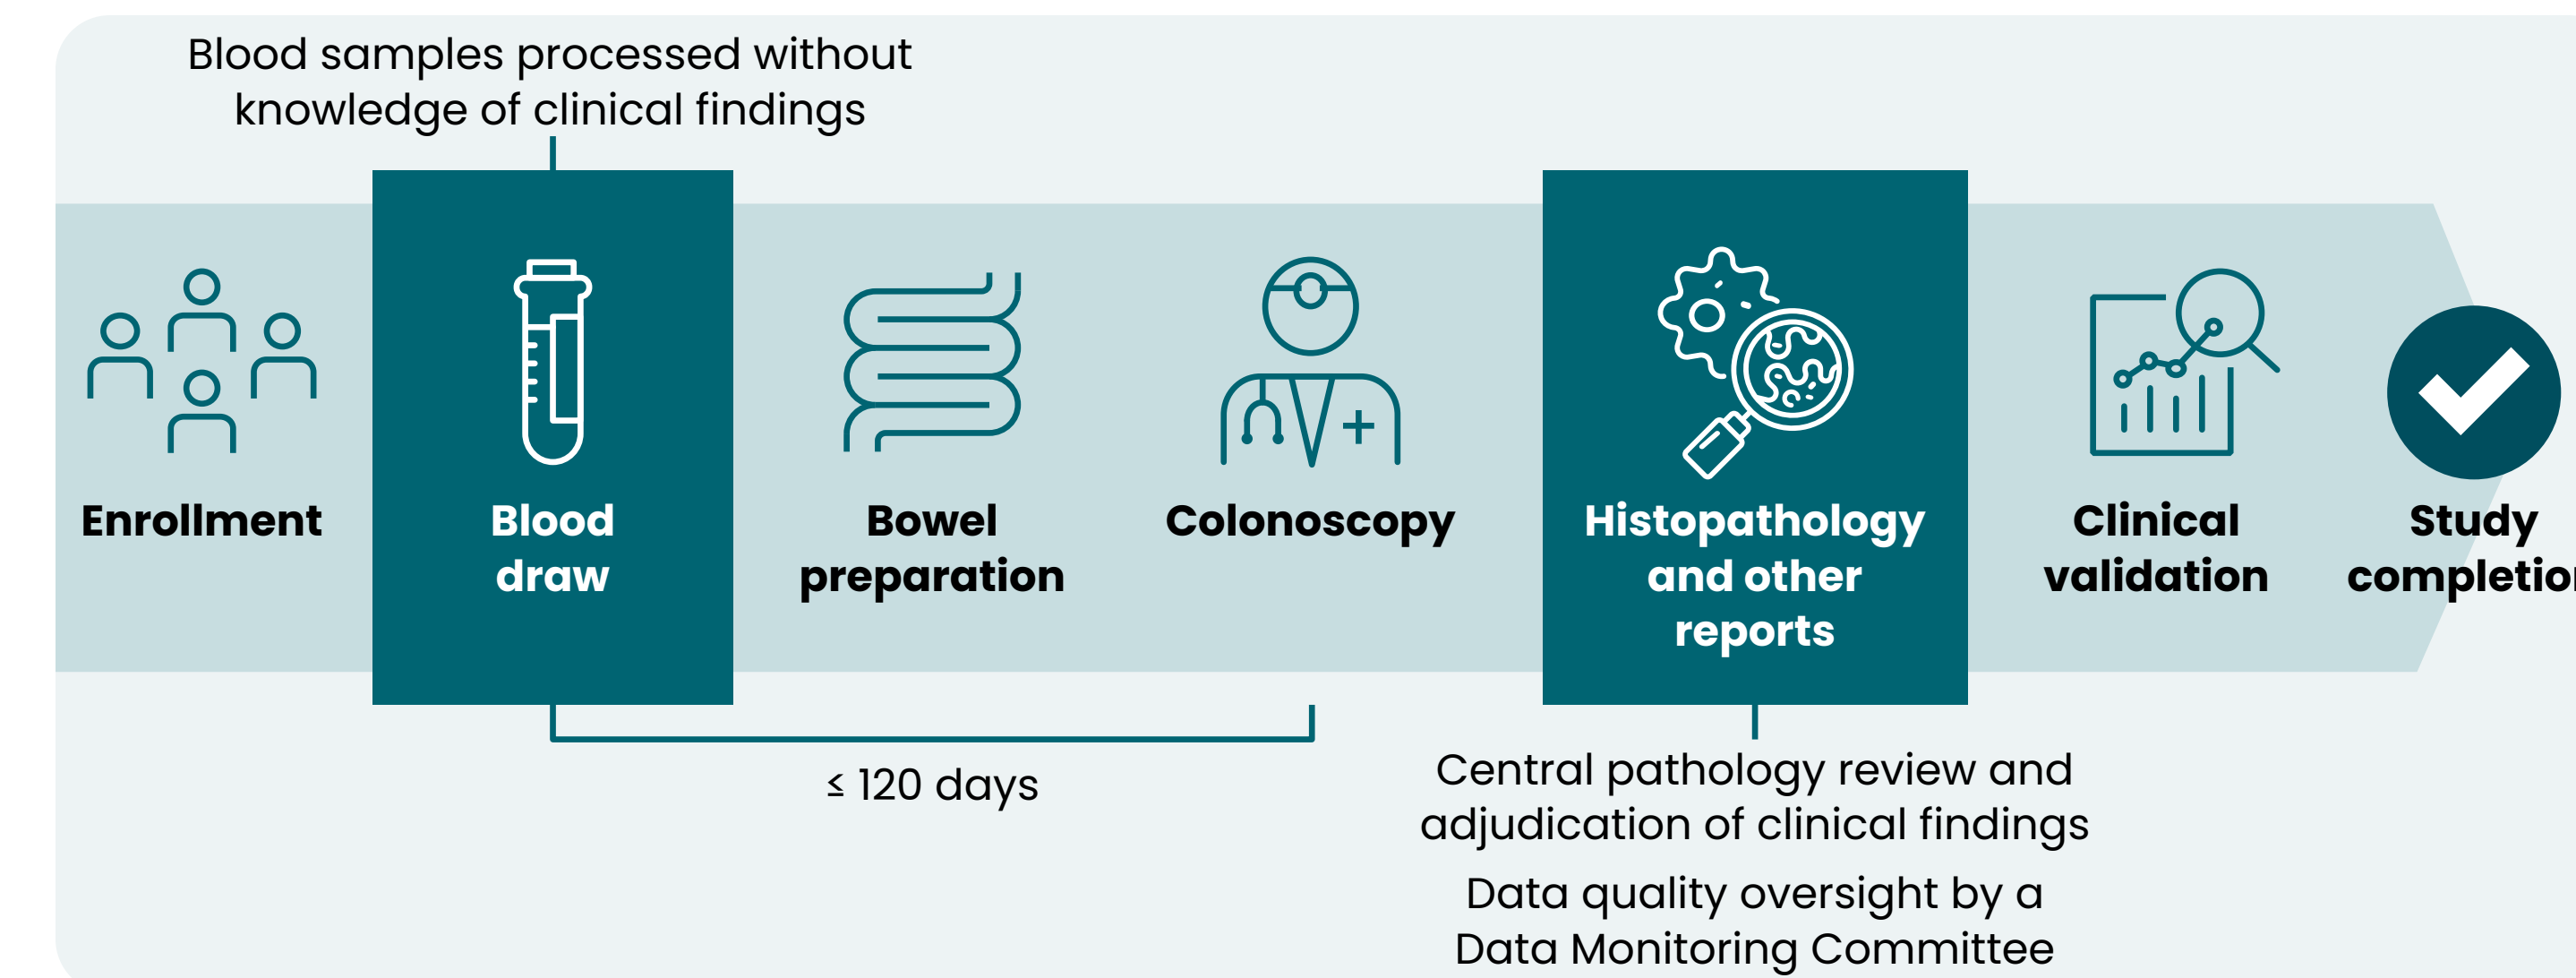

- Participants had to be 45 to 85 years of age, at average risk for CRC, and willing to undergo a standard-of-care screening CS to be eligible for enrollment
- Prior to bowel preparation for CS, participants provided a blood sample that was sent to Freenome for testing

KEY FINDINGS AND CONCLUSIONS

- PREEMPT CRC is the largest prospective study to date of a blood-based screening test for CRC in an average-risk population
- With a sensitivity for CRC of 79.2% and specificity for ACN of 91.5%, the investigational CRC early detection blood test met all primary endpoints
- The test was able to detect CRC lesions across a wide range of sizes, with test sensitivity increasing as lesion size increased
- The test effectively detected CRC throughout the colon and displayed a 100% sensitivity for CRC lesions located in the proximal colon
 - When controlling for demographic characteristics and lesion size, lesion location was not found to be a variable contributing to test sensitivity for CRC
- Performance of the CRC early detection blood test in PREEMPT CRC indicates that blood-based screening tests may offer an effective alternative for early CRC detection in average-risk individuals

- CS was performed within 120 days of the blood draw (Figure 1)
- CS and applicable histopathology reports underwent central review
- Blood samples were processed blind to clinical findings, and all participants, research physicians, and central pathologists remained blind to the results of the blood test

Figure 1. PREEMPT CRC Study Schema

Test validation

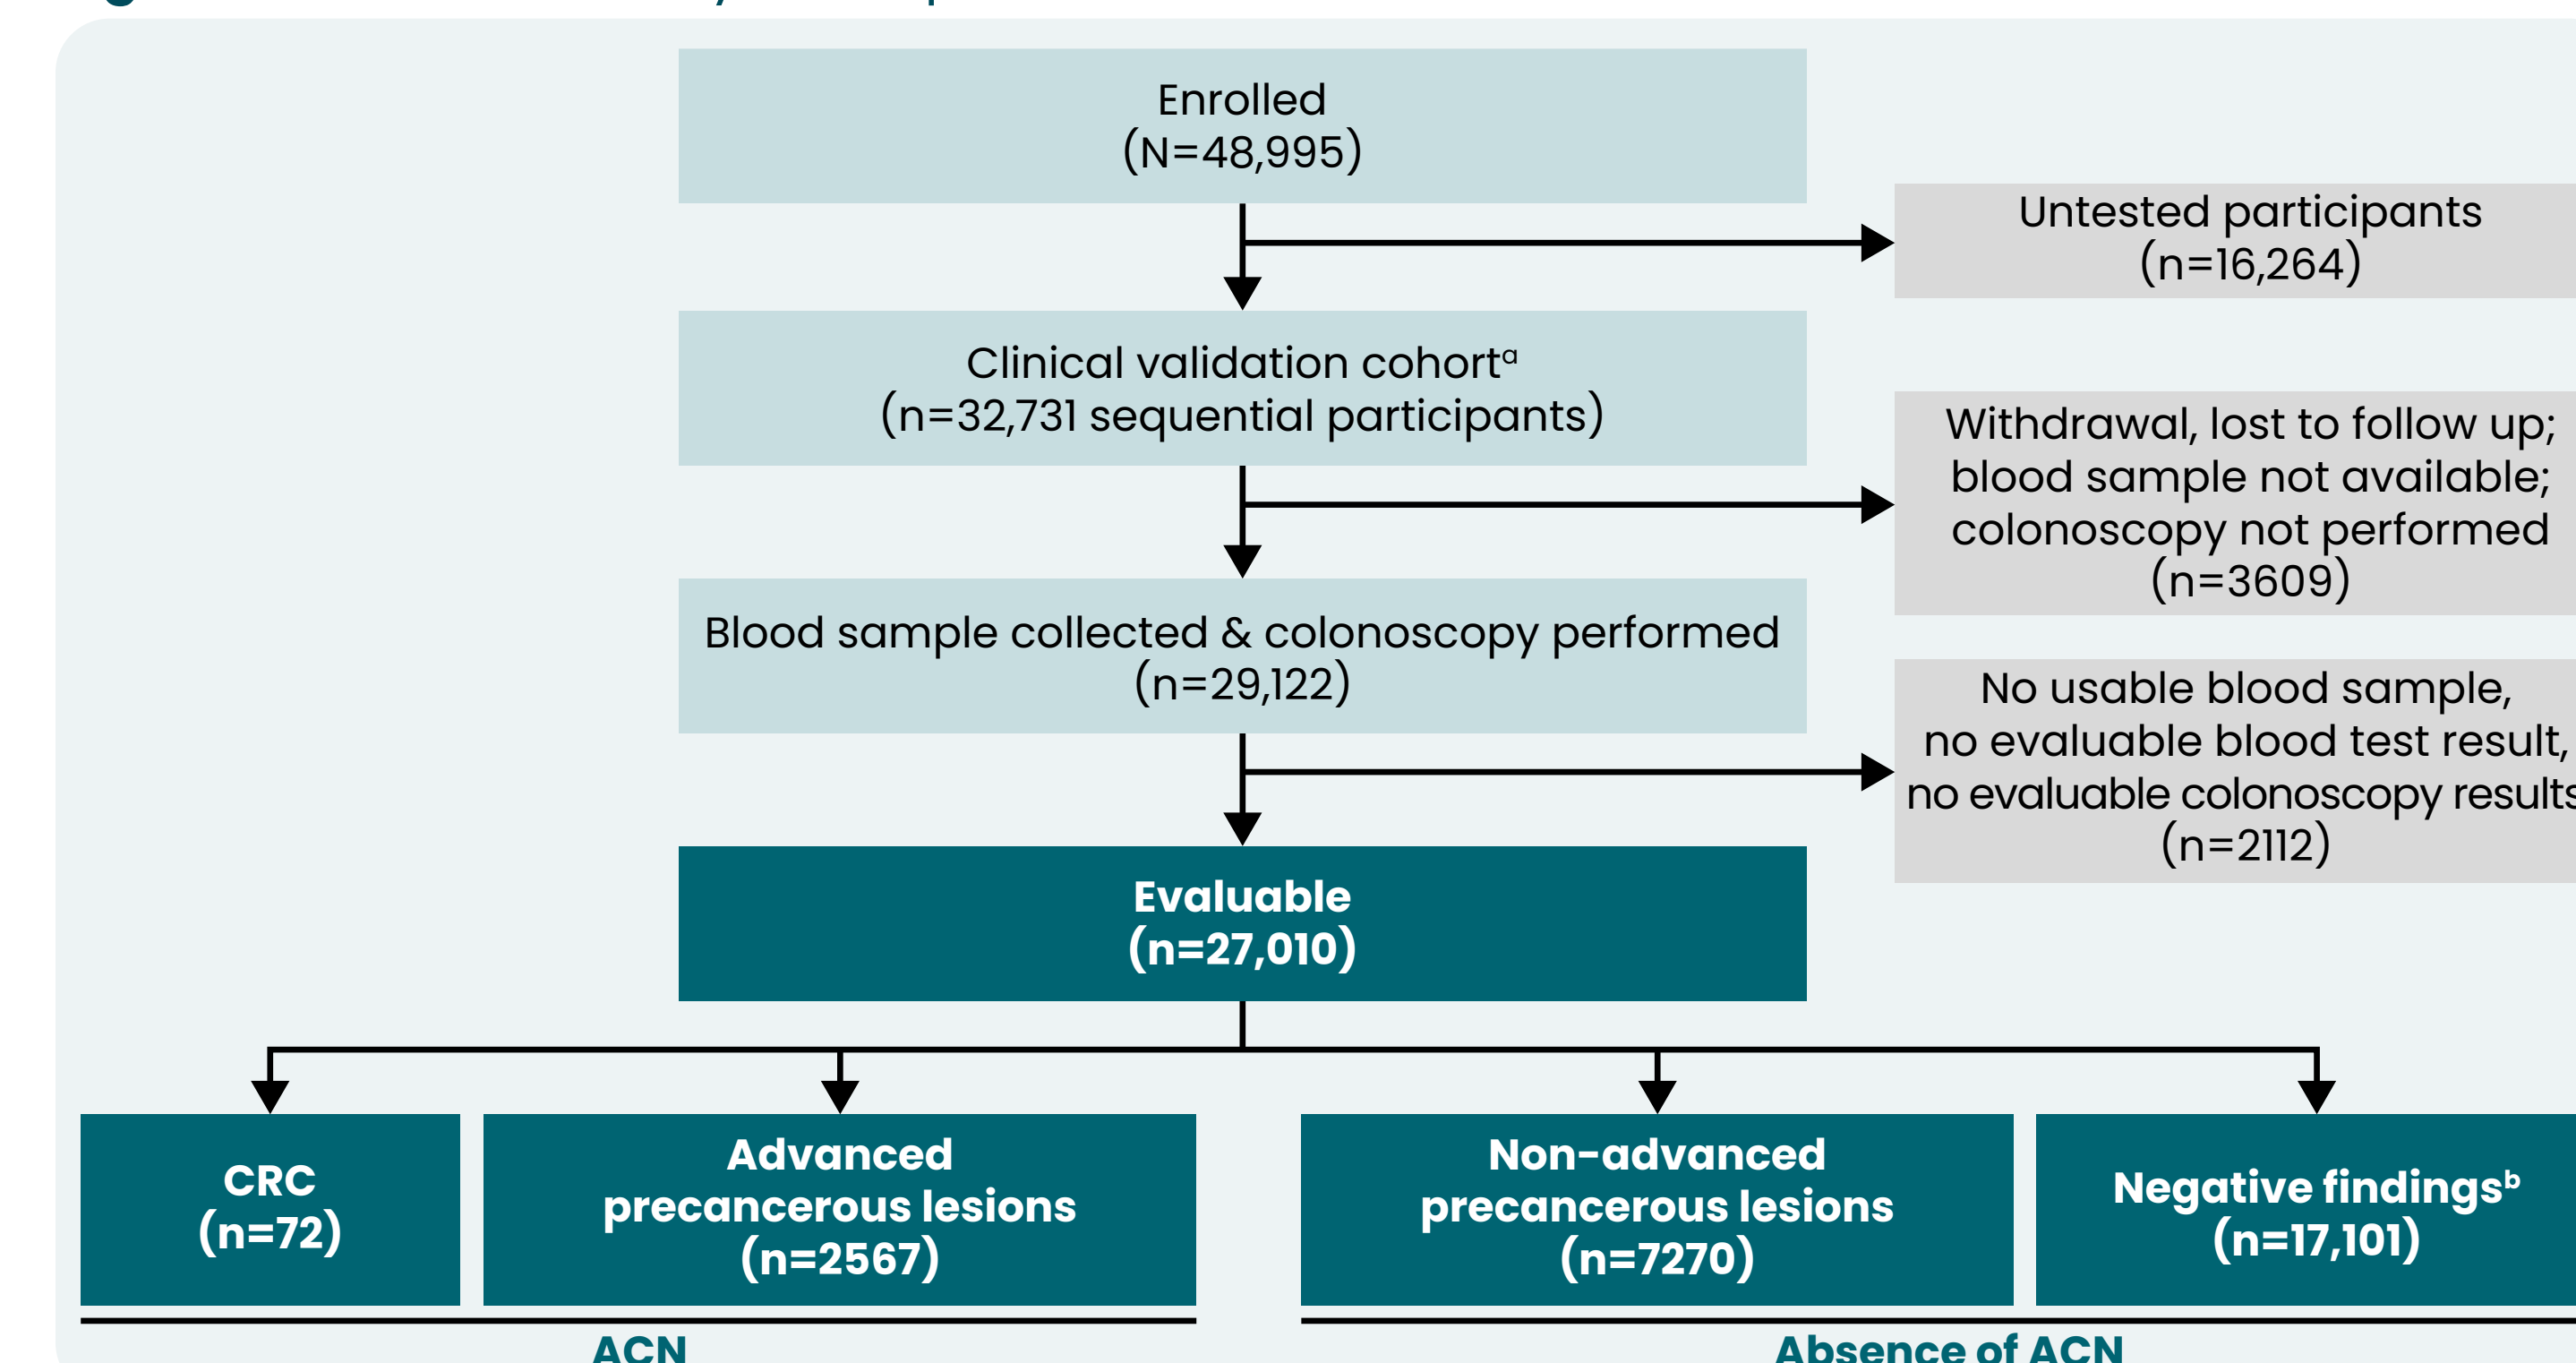

- The performance of the CRC early detection blood test was assessed using screening CS with histopathology as the reference method
- The prespecified four co-primary endpoints included sensitivity for CRC, specificity for ACN, negative predictive value (NPV) for ACN, and positive predictive value (PPV) for ACN
 - ACN comprised CRC and advanced precancerous lesions
 - Advanced precancerous lesions included carcinoma *in situ* or high-grade dysplasia, adenoma with villous growth pattern (≥25%), adenoma ≥1.0 cm, sessile serrated lesion with or without cytological dysplasia ≥1.0 cm, and traditional serrated adenoma
- A prespecified multivariate logistic regression analysis was performed to assess the test positivity for CRC, adjusting for lesion location, lesion size, and demographic characteristics

RESULTS

Participant demographics

- Out of 48,995 study participants originally enrolled in PREEMPT CRC between May 2020 and April 2022, a subset of 32,731 sequentially enrolled participants were included in the clinical validation cohort (Figure 2)
 - Of these, 82.5% (n=27,010) had evaluable blood samples and CS results

Figure 2. Evaluable Study Participants

^aThe clinical validation cohort included 32,731 participants consecutively enrolled after a predetermined cutoff date that corresponded to expanded eligibility of COVID-19 vaccination for the overall population and a return to more normal office visits.
^bNegative findings include non-neoplastic or no findings.
 ACN, advanced colorectal neoplasia; CRC, colorectal cancer.

- The mean age of participants was 58.1 years and 55.8% were female
- The study enrolled a diverse population, with 11.2% of participants identifying as Black or African American, 8.8% identifying as Asian, and 11.8% identifying as Hispanic or Latino (Table 1)

Table 1. Baseline Demographics of Evaluable Participants

Demographic characteristics	Evaluable participants (N=27,010)
Age, years	
Mean (SD)	58.1 (8.2)
Median	57.0
Age group, n (%)	
45–49	2968 (11.0)
50–54	8899 (32.9)
55–64	8725 (32.3)
65–74	5604 (20.7)
≥75	814 (3.0)
Biological sex, n (%)	
Female	15,076 (55.8)
Male	11,934 (44.2)
Race, n (%)	
White	19,707 (73.0)
Black or African American	3038 (11.2)
Asian	2381 (8.8)
American Indian or Alaskan Native	78 (0.3)
Native Hawaiian or Other Pacific Islander	72 (0.3)
More than one reported	136 (0.5)
Other/unknown	1598 (5.9)
Ethnicity, n (%)	
Hispanic or Latino	3189 (11.8)
Not Hispanic or Latino	22,421 (83.0)
Unknown	1400 (5.2)

Percentages may not total 100 because of rounding.

Test performance for primary outcome measures

- PREEMPT CRC met all primary endpoints (Table 2)

Table 2. Test Performance for Primary Outcome Measures in Evaluable Participants

Endpoint	Total evaluated (n/N)	% (95% CI)
Sensitivity for CRC	57/72	79.2% (68.4%–86.9%)
Specificity for ACN	22,306/24,371	91.5% (91.2%–91.9%)
NPV for ACN	22,306/24,567	90.8% (90.7%–90.9%)
PPV for ACN	378/2443	15.5% (14.2%–16.8%)

ACN, advanced colorectal neoplasia; CRC, colorectal cancer; NPV, negative predictive value; PPV, positive predictive value.

Test performance by CRC stage, lesion size, and lesion location

- Test sensitivity was 57.1% (95% CI, 39.1%–73.5%) for stage I, 100% (95% CI, 79.6%–100%) for stage II, 82.4% (95% CI, 59.0%–93.8%) for stage III and 100% (95% CI, 74.1%–100%) for stage IV (Figure 3)

Figure 3. Test Sensitivity for CRC by Stage

Stage was reported for all except one CRC case, which was detected by the blood test. Stages were defined by the American Joint Committee on Cancer Staging System, 8th edition.¹¹ Error bars indicate 95% CIs. CRC, colorectal cancer.

- Test sensitivity for CRC and lesion size were directly proportional, with sensitivity increasing as lesion size increased (Figure 4)
 - Sensitivity for CRC was 33.3% (95% CI, 6.1%–79.2%) for lesions of 6 to 9 mm, 50.0% (95% CI, 23.7%–76.3%) for lesions of 10 to 19 mm, 90.9% (95% CI, 62.3%–98.4%) for lesions of 20 to 29 mm, and 92.7% (95% CI, 80.6%–97.5%) for lesions ≥30 mm
- Sensitivity for CRC was 100% (95% CI, 74.1%–100.0%) for lesions located in the proximal colon, 66.7% (95% CI, 49.6%–80.2%) for lesions in the distal colon, and 85.7% (95% CI, 68.5%–94.3%) for lesions in the rectum (Figure 4)
- In the prespecified multivariate logistic regression analysis, no statistically significant difference in test sensitivity by lesion location was found when adjusting for demographic characteristics (age, sex, and race) and lesion size

Figure 4. Test Sensitivity for CRC by Lesion Size and Location

^aLesion size was reported for all except two CRC cases. Error bars indicate 95% CIs. CRC, colorectal cancer.

Study design

- Participants had to be 45 to 85 years of age, at average risk for CRC, and willing to undergo a standard-of-care screening CS to be eligible for enrollment
- Prior to bowel preparation for CS, participants provided a blood sample that was sent to Freenome for testing
- CS was performed within 120 days of the blood draw (**Figure 1**)
- CS and applicable histopathology reports underwent central review
- Blood samples were processed blind to clinical findings, and all participants, research physicians, and central pathologists remained blind to the results of the blood test

Figure 1. PREEMPT CRC Study Schema

^aThe clinical validation cohort included 32,731 participants consecutively enrolled after a predetermined cutoff date that corresponded to expanded eligibility of COVID-19 vaccination for the overall population and a return to more normal office visits.
^bNegative findings include non-neoplastic or no findings.
 ACN, advanced colorectal neoplasia; CRC, colorectal cancer.

Sensitivity for CRC	57/72	79.2% (68.4%–86.9%)
Specificity for ACN	22,306/24,371	91.5% (91.2%–91.9%)
NPV for ACN	22,306/24,567	90.8% (90.7%–90.9%)
PPV for ACN	378/2443	15.5% (14.2%–16.8%)

ACN, advanced colorectal neoplasia; CRC, colorectal cancer; NPV, negative predictive value; PPV, positive predictive value.

CRC by stage, lesion size, and lesion location

(95% CI, 39.1%–73.5%) for stage I, 100% (95% CI, 79.6%–100%) for stage II, 99.0%–93.8% for stage III and 100% (95% CI, 74.1%–100%) for stage IV

CRC by Stage

0 CRC cases, which was detected by the blood test. Stages were defined by the American Joint Committee on Cancer (AJCC) staging system. Error bars indicate 95% CIs.

Lesion size and location were directly proportional, with sensitivity increasing as lesion size increased (Figure 4)

Sensitivity for lesions of 6 to 9 mm, 50.0% (95% CI, 33.3%–66.7%) for lesions of 10 to 19 mm, 90.9% (95% CI, 80.6%–97.5%) for lesions of 20 to 29 mm, and 100% (95% CI, 74.1%–100.0%) for lesions of 30 mm or greater

Sensitivity for lesions in the proximal colon, 100% (95% CI, 74.1%–100.0%) for lesions in the distal colon, and 85.7% (95% CI, 68.5%–94.3%) for lesions in the rectum (Figure 4)

In a multivariate logistic regression analysis, no statistically significant association between lesion location and sensitivity by lesion location was found when adjusting for demographic characteristics (age, sex, and race) and lesion size

CRC by Lesion Size and Location

0 CRC cases. Error bars indicate 95% CIs.

INTRODUCTION

- Colorectal cancer (CRC) is the second-leading cause of cancer but is treatable when detected early¹
- Despite the proven benefits of CRC screening, recent statistics reveal that adults at average risk for CRC in the US were not up to date with screening in 2021²⁻⁴
- Low screening uptake can partly be attributed to the inconvenience of existing screening methods and disparities in access to medical services among demographic groups^{5,6}
- Specific challenges of current screening modalities include bowel preparation, invasiveness associated with colonoscopy (CS), and fecal aversion associated with stool-based tests⁷
- Ideally, comprehensive CRC screening should detect both small colorectal neoplasia (ACN) and difficult-to-discern proximal lesions with a high likelihood of achieving the best possible outcomes⁸
- Blood-based screening may offer a convenient alternative to CS that potentially increase screening uptake^{9,10}
- PREEMPT CRC (NCT04369053¹¹), a prospective, multicenter, observational study conducted to validate an investigational CRC early detection blood test that detects molecular signals associated with ACN in an average-risk population

OBJECTIVE

- To analyze the performance of an investigational CRC early detection blood test by lesion location and size

METHODS

Study design

- Participants had to be 45 to 85 years of age, at average risk for CRC, and not on a standard-of-care screening CS to be eligible for enrollment
- Prior to bowel preparation for CS, participants provided a blood sample for the investigational CRC early detection blood test and a stool sample for CS. Freenome for testing

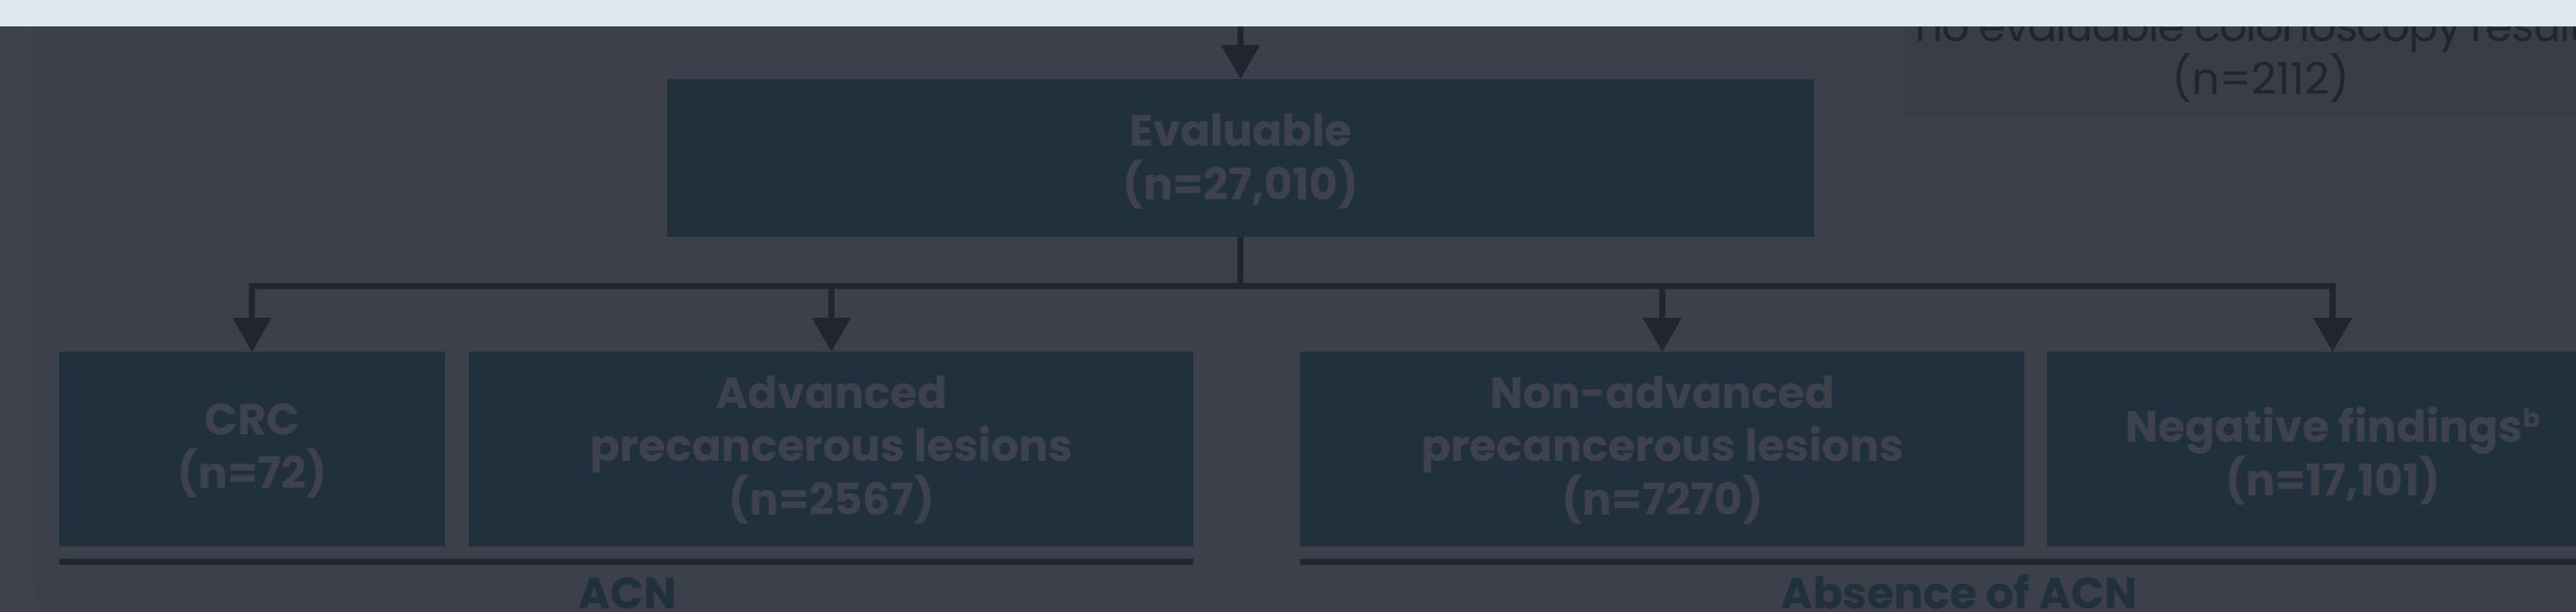

KEY FINDINGS AND CONCLUSIONS

- PREEMPT CRC is the largest prospective study to date evaluating a blood-based screening test for CRC in an average-risk population
- With a sensitivity for CRC of 79.2% and specificity for ACN of 91.5%, the investigational CRC early detection blood test met its primary endpoints
- The test was able to detect CRC lesions across a wide range of lesion sizes, with test sensitivity increasing as lesion size increased
- The test effectively detected CRC throughout the colon, with a 100% sensitivity for CRC lesions located in the proximal colon
- When controlling for demographic characteristics and lesion size, lesion location was not found to be a variable contributing to test sensitivity for CRC
- Performance of the CRC early detection blood test in PREEMPT CRC indicates that blood-based screening tests may offer an effective alternative for early CRC detection in average-risk individuals

METHODS

Test validation

- The performance of the CRC early detection blood test was assessed using screening CS with histopathology as the reference method
- The prespecified four co-primary endpoints included sensitivity for CRC, specificity for ACN, negative predictive value (NPV) for ACN, and positive predictive value (PPV) for ACN
 - ACN comprised CRC and advanced precancerous lesions
 - Advanced precancerous lesions included carcinoma *in situ* or high-grade dysplasia, adenoma with villous growth pattern ($\geq 25\%$), adenoma ≥ 1.0 cm, sessile serrated lesion with or without cytological dysplasia ≥ 1.0 cm, and traditional serrated adenoma
- A prespecified multivariate logistic regression analysis was performed to assess the test positivity for CRC, adjusting for lesion location, lesion size, and demographic characteristics

*The clinical validation cohort included 32,731 participants consecutively enrolled after a predetermined cutoff date that corresponded to expanded eligibility of COVID-19 vaccination for the overall population and a return to more normal office visits.

*Negative findings include non-neoplastic or no findings.

ACN, advanced colorectal neoplasia; CRC, colorectal cancer.

Sensitivity for CRC	57/72	79.2% (68.4%–86.9%)

White	19,707 (73.0)
Black or African American	3038 (11.2)
Asian	2381 (8.8)
American Indian or Alaskan Native	78 (0.3)
Native Hawaiian or Other Pacific Islander	72 (0.3)
More than one reported	136 (0.5)
Other/unknown	1598 (5.9)
Ethnicity, n (%)	
Hispanic or Latino	3189 (11.8)
Not Hispanic or Latino	22,421 (83.0)
Unknown	1400 (5.2)

Percentages may not total 100 because of rounding.

^aThe clinical validation cohort included 32,731 participants consecutively enrolled after a predetermined cutoff date that corresponded to expanded eligibility of COVID-19 vaccination for the overall population and a return to more normal office visits.

^bNegative findings include non-neoplastic or no findings.

ACN, advanced colorectal neoplasia; CRC, colorectal cancer.

CRC by Stage, Lesion Size, and Lesion Location

Sensitivity for CRC was 100% (95% CI, 99.0%–100.0%) for stage I, 100% (95% CI, 79.6%–100%) for stage II, 82.4% (95% CI, 79.0%–93.8%) for stage III and 100% (95% CI, 74.1%–100%) for stage IV

CRC by Stage

^aOne CRC case, which was detected by the blood test. Stages were defined by the American Joint Committee on Cancer. Error bars indicate 95% CIs.

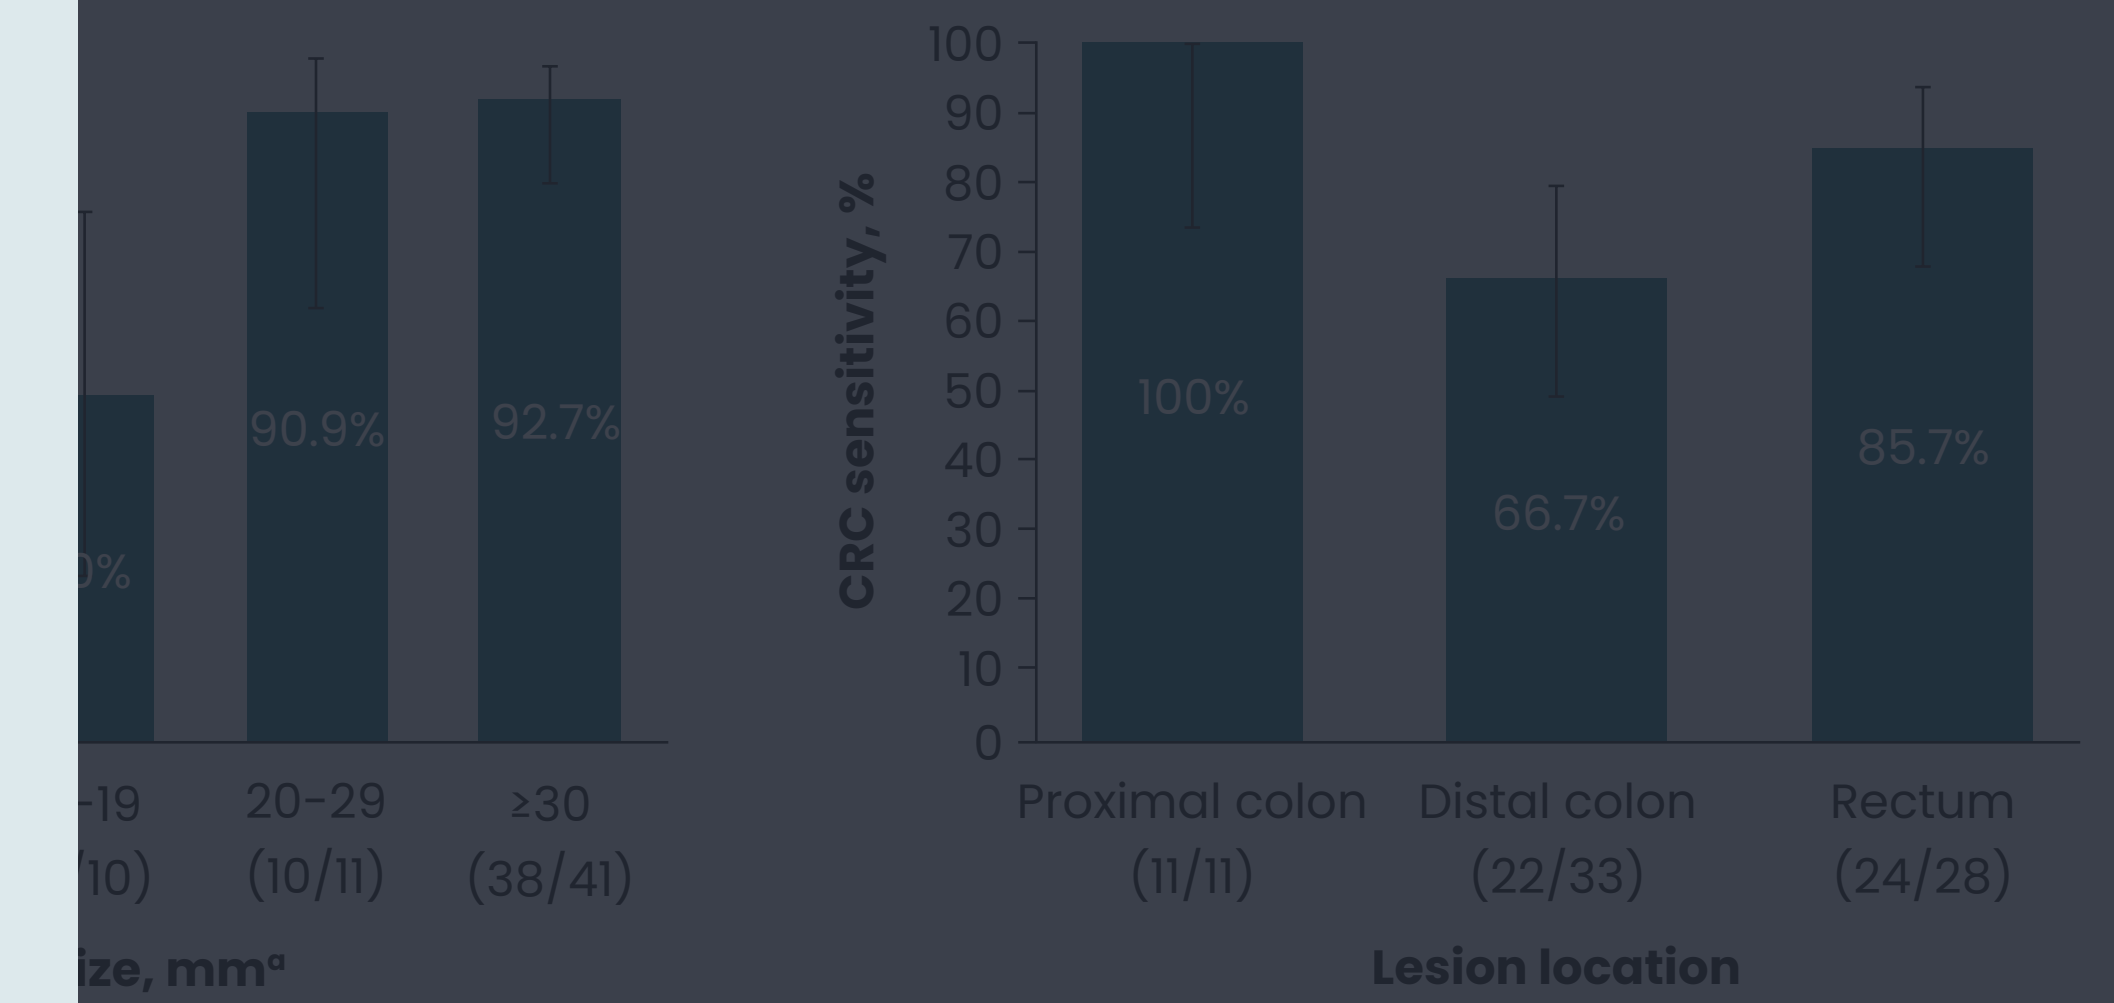

Lesion size and location were directly proportional, with sensitivity increasing as lesion size increased (Figure 4)

Sensitivity for CRC was 33.3% (95% CI, 6.1%–79.2%) for lesions of 6 to 9 mm, 50.0% (95% CI, 33.3%–66.7%) for lesions of 10 to 19 mm, 90.9% (95% CI, 62.3%–98.4%) for lesions of 20 to 29 mm, and 92.7% (95% CI, 80.6%–97.5%) for lesions ≥30 mm

Sensitivity for CRC was 100% (95% CI, 74.1%–100.0%) for lesions located in the proximal colon, 68.7% (95% CI, 50.2%–85.7%) for lesions in the distal colon, and 85.7% (95% CI, 68.5%–94.3%) for lesions in the rectum (Figure 4)

In multivariate logistic regression analysis, no statistically significant association between lesion location and sensitivity by lesion location was found when adjusting for demographic characteristics (age, sex, and race) and lesion size

CRC by Lesion Size and Location

^aProximal colon, distal colon, and rectum. Error bars indicate 95% CIs.

^aAffiliation at the time the study and/or analyses were conducted

INTRODUCTION

- Colorectal cancer (CRC) is the second-leading cause of cancer but is treatable when detected early¹
- Despite the proven benefits of CRC screening, recent statistics reveal that adults at average risk for CRC in the US were not up to date with screening in 2021²⁻⁴
- Low screening uptake can partly be attributed to the inconvenience of existing screening methods and disparities in access to medical services among demographic groups^{5,6}
- Specific challenges of current screening modalities include bowel preparation, invasiveness associated with colonoscopy (CS), and fecal aversion associated with stool-based tests⁷
- Ideally, comprehensive CRC screening should detect both small colorectal neoplasia (ACN) and difficult-to-discern proximal lesions, with a high likelihood of achieving the best possible outcomes⁸
- Blood-based screening may offer a convenient alternative to CS that potentially increase screening uptake^{9,10}
- PREEMPT CRC (NCT04369053¹¹), a prospective, multicenter, observational study conducted to validate an investigational CRC early detection blood test that detects molecular signals associated with ACN in an average-risk population.

OBJECTIVE

- To analyze the performance of an investigational CRC early detection blood test in terms of sensitivity, specificity, NPV, and PPV by lesion location and size

METHODS

Study design

- Participants had to be 45 to 85 years of age, at average risk for CRC, and not on a standard-of-care screening CS to be eligible for enrollment
- Prior to bowel preparation for CS, participants provided a blood sample for the investigational CRC early detection blood test (Freenome) for testing

KEY FINDINGS AND CONCLUSIONS

- PREEMPT CRC is the largest prospective study to date evaluating a blood-based screening test for CRC in an average-risk population
- With a sensitivity for CRC of 79.2% and specificity for ACN of 91.5%, the investigational CRC early detection blood test met all primary endpoints
- The test was able to detect CRC lesions across a wide range of lesion sizes, with test sensitivity increasing as lesion size increased
- The test effectively detected CRC throughout the colon, with a 100% sensitivity for CRC lesions located in the proximal colon
- When controlling for demographic characteristics and lesion size, lesion location was not found to be a variable contributing to test sensitivity for CRC
- Performance of the CRC early detection blood test in PREEMPT CRC indicates that blood-based screening tests may offer an effective alternative for early CRC detection in average-risk individuals

RESULTS

Test performance for primary outcome measures

- PREEMPT CRC met all primary endpoints (**Table 2**)

Table 2. Test Performance for Primary Outcome Measures in Evaluable Participants

Endpoint	Evaluable participants (N=27,010)	
	Total evaluated (n/N)	% (95% CI)
Sensitivity for CRC	57/72	79.2% (68.4%–86.9%)
Specificity for ACN	22,306/24,371	91.5% (91.2%–91.9%)
NPV for ACN	22,306/24,567	90.8% (90.7%–90.9%)
PPV for ACN	378/2443	15.5% (14.2%–16.8%)

ACN, advanced colorectal neoplasia; CRC, colorectal cancer; NPV, negative predictive value; PPV, positive predictive value.

*The clinical validation cohort included 32,731 participants consecutively enrolled after a predetermined cutoff date that corresponded to expanded eligibility of COVID-19 vaccination for the overall population and a return to more normal office visits.

*Negative findings include non-neoplastic or no findings.

ACN, advanced colorectal neoplasia; CRC, colorectal cancer.

Sensitivity for CRC	57/72	79.2% (68.4%–86.9%)
Specificity for ACN	22,306/24,371	91.5% (91.2%–91.9%)
NPV for ACN	22,306/24,567	90.8% (90.7%–90.9%)
PPV for ACN	378/2443	15.5% (14.2%–16.8%)

ACN, advanced colorectal neoplasia; CRC, colorectal cancer; NPV, negative predictive value; PPV, positive predictive value.

CRC by stage, lesion size, and lesion location

(95% CI, 39.1%–73.5%) for stage I, 100% (95% CI, 79.6%–100%) for stage II, 99.0%–93.8% for stage III and 100% (95% CI, 74.1%–100%) for stage IV

CRC by Stage

0 CRC cases, which was detected by the blood test. Stages were defined by the American Joint Committee on Cancer. Error bars indicate 95% CIs.

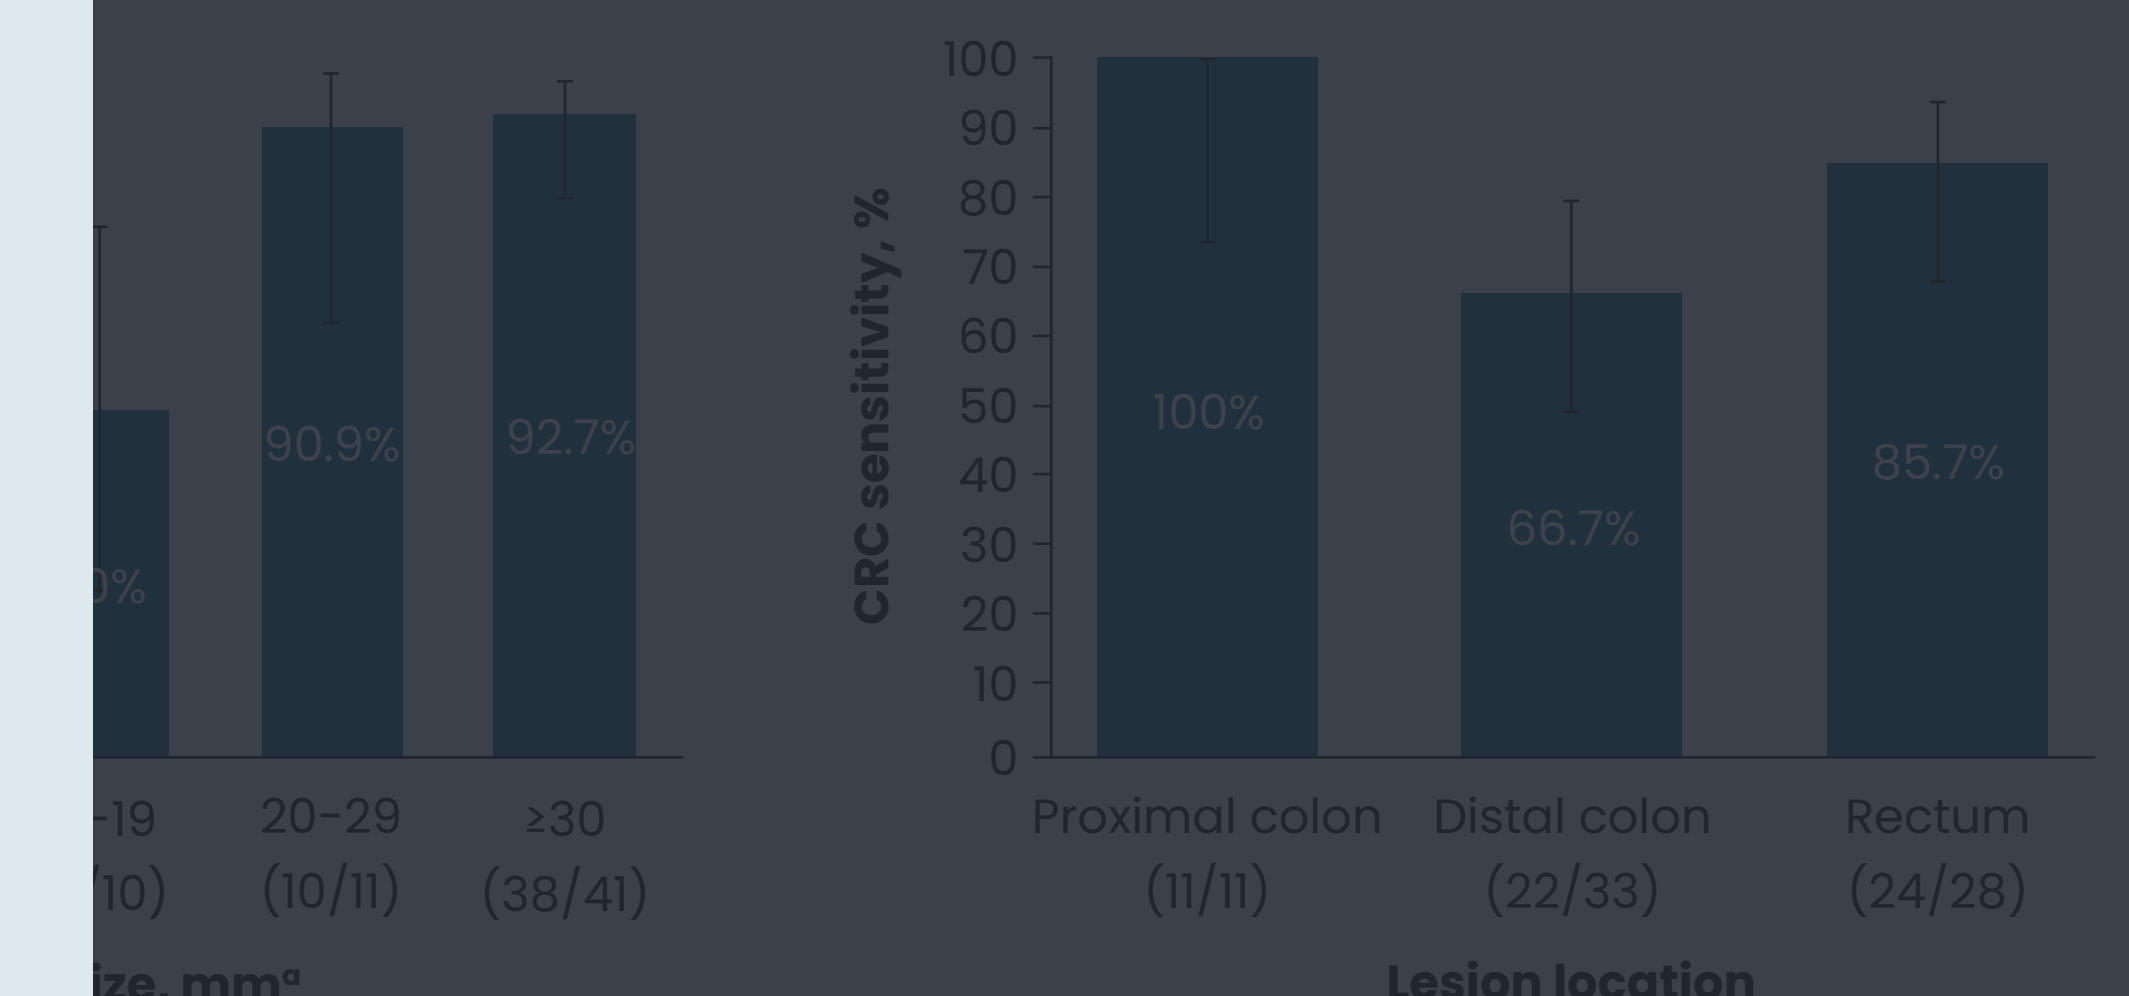

and lesion size were directly proportional, with sensitivity increasing as lesion size increased (Figure 4)

Sensitivity for CRC was 33.3% (95% CI, 6.1%–79.2%) for lesions of 6 to 9 mm, 50.0% (95% CI, 25.0%–75.0%) for lesions of 10 to 19 mm, 90.9% (95% CI, 62.3%–98.4%) for lesions of 20 to 29 mm, and 92.7% (95% CI, 80.6%–97.5%) for lesions ≥30 mm

Sensitivity for CRC was 100% (95% CI, 74.1%–100.0%) for lesions located in the proximal colon, 66.7% (95% CI, 44.4%–89.0%) for lesions in the distal colon, and 85.7% (95% CI, 68.5%–94.3%) for lesions in the rectum (Figure 4)

In a multivariate logistic regression analysis, no statistically significant association between lesion location and test sensitivity was found when adjusting for demographic characteristics (age, sex, and race) and lesion size

CRC by Lesion Size and Location

0 CRC cases. Error bars indicate 95% CIs.
